ABSTRACT

This study develops a newly designed, patented, bidirectional dc/dc converter (BDC) that interfaces a main energy storage (ES1), an auxiliary energy storage (ES2), and dc-bus of different voltage levels, for application in hybrid electric vehicle systems. The proposed converter can operate in a step-up mode (i.e., low-voltage dual-source-powering mode) and a step-down (i.e., high-voltage dc-link energy-regenerating mode), both with bidirectional power flow control. In addition, the model can independently control power flow between any two low-voltage sources (i.e., low-voltage dual-source buck/boost mode). Herein, the circuit configuration, operation, steady-state analysis, and closed-loop control of the proposed BDC are discussed according to its three modes of power transfer. Moreover, the simulation are provided to validate the proposed converter.

KEYWORDS— Autonomous energy management system, pluginelectric vehicle, energy storage, bidirectional charger, grid-to-vehicle and vehicle-to-grid.

Introduction

The continuous rise in gasoline prices along with the increased concerns about the pollutions produced by fossil fuel engines are forcing the current vehicle market to find new alternatives to reduce the fossil fuel usage. Along with the research on bio-fuel driven engines; different electric vehicles and hybrid electric vehicles are evolving as viable alternatives to replace, or at least reduce, the current fleet of fossil fuel driven vehicles. Although current manufactured electric/hybrid vehicles are being marketed as a way to reduce fossil fuel usage, several promising technologies are being demonstrated that can utilize power electronics to charge the battery from the utility using plug-in vehicles or act as a distributed resource to send power back to the utility with vehicle-to-grid capabilities. In this paper,

different plug-in vehicle topologies are described to review the power electronics required for them. The newly evolving V2G technology is also discussed along with economics and compliance requirements to allow the vehicle to be connected to the grid. Before going into the details of power electronics required for the electric/hybrid vehicles, the common forms of these vehicles are described next to get accustomed with the terminologies.

Electric Vehicles

A typical electric vehicle (EV) has a battery pack connected to an electric motor and provides traction power through the use of a transmission. The batteries are charged primarily by a battery charger that receives its power from an external source such as the electrical utility. Also during regenerative braking, the motor acts as a generator which provides power back to the batteries and in the process slows down the vehicle. The primary advantage of an EV is that the design is simple and has a low part count. The primary disadvantage is that the driving range of the vehicle is limited to the size of the battery and the time to re-charge the battery can be from 15 minutes to 8 hours depending on how far the vehicle was last driven, the battery type and battery charging method.

Hybrid Electric Vehicles

The components that make up a typical hybrid electric vehicle (HEV) include a battery pack, motor controller, motor/generator, internal combustion engine, transmission and driveline components. The batteries are charged through the use of the on-board internal combustion engine and generator. In a plug-in hybrid electric vehicle (PHEV), the batteries can also be charged through the use of a battery charger that receives its power from the utility. The best PHEV design will allow the vehicle to operate on electric power only reducing the amount of time that the engine runs. When the vehicle is not operating, the battery can be charged through the use of a battery charger that is "plugged in" to the electrical utility or other energy sources. A PHEV normally has a larger battery pack than a HEV. The advantage of a PHEV over an HEV is that due to external battery charging, the vehicle can run longer on electric power which in-turn reduces engine fuel consumption.

Fuel Cell Vehicles

The prototype fuel cell vehicles (FCV) that are currently under development mostly utilize an on-board tank to store pressurized hydrogen. Hydrogen and conditioned air are fed to a proton exchange membrane (PEM) stack to develop DC power. The configuration is very similar to the electric vehicle configuration in which a electric motor/generator provides the mechanical power for traction. The on-board batteries allow the energy to be stored during regenerative braking and provide peak power to the motor controller during vehicle acceleration. A plug-in fuel cell vehicle (PFCV) has a battery pack and a fuel cell that is connected to an electric motor that provides traction power to the wheels through a transmission.

The batteries can be charged by the use of a battery charger that receives its power from the utility but can also be charged by using the fuel cell.

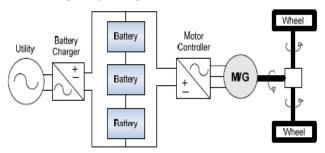

Figure 1: Typical EV configuration

Plug-In Vehicles:

According to the Electric Power Research Institute (EPRI), more than 40% of U.S. generating capacity operates overnightat a reduced load overnight, and it is during these off-peakhours that most PHEVs could be recharged. Recent studies show that if PHEVs replace one-half of all vehicles on the roadby 2050, only an 8% increase in electricity generation (4%increase in capacity) will be required [2]. Most of the electric vehicles that are of plug-in type, utilizeon-board battery chargers to recharge the batteries using utilitypower. The simplest form of a plug-in electric vehicle is shownin Fig. 1. This configuration consists of a battery system and amotor controller that provides power to the motor, which in-turnsupplies power to the wheels for traction. Many of today's EVs use a permanent magnet electric motor that can also act as a generator to recharge the batteries when the brakes areapplied. During regenerative braking, the motor acts as agenerator that provides power back to the batteries and in theprocess slows down the vehicle. Friction brakes are used whenthe vehicle must be stopped quickly or if the batteries are atfull charge.

The components that make up a typical HEV include abattery pack, motor controller, motor/generator, internalcombustion engine, transmission and driveline components. The primary power electronics include a DC-AC motorcontroller which provides three-phase power to a permanentmagnet motor. The Toyota Prius HEV configuration is givenin Fig. 2. The Prius design uses two permanent magnetmotors/generator, one of 10kW and the other of 50kW. Thebattery is connected to booster and inverter before feeding tothe motor/generators. The power electronics are

bidirectionaland used for both charging the battery and powering themotors. The motor/generators gasoline engine feed into aplanetary gear set. The system operates in a continuously variable transmission (CVT) mode where the gear ratio is determined by the power transfer between the battery, motor/generators and gasoline engine [3], [4]. The batteries canalso be using regenerative braking largemotor/generators. There is no provision to charge the batteriesexternally.For plug-in hybrid electric vehicles, batteries are chargedwhen they are not being driven. This is normally accomplished through a utility connected AC-DC converter to obtain DCpower from the grid. The batteries can also be charged directly from a solar resource using a DC-DC converter or from a windsource using an AC-DC converter. Energy flow isunidirectional as power is taken from the utility to charge thebattery pack. A Toyota Prius configuration with PHEVconversion is shown in Fig. 2.The battery voltage for most converted PHEVs aremaintained at the same level as the original design (typically200-500 VDC) and battery modules are added in parallel toincrease the energy capacity of the battery pack, thus allowingthe electric motor to run more often than the original HEVdesign. Some of the PHEV conversion companies include:CalCars, Energy CS, Hymotion, Electrovaya, and HybridsPlus, and most of them use lithium batteries.

Plug-in Electric Vehicle Charger Topology

The desirable characteristics for the charger are power bi-directionality(V2G and G2V), power factor equal to one, capabilityof performing power control, low PQ impact, constructionand topology simplicity, and regular 16 A single-phase plugcompatibility [6].

This charger does not allow performing fastcharge, being 2.3 kW (10 A, 230 V) the advisable maximumpower for a single-phase household-type plug. Thispower range is defined based on EU standards and power gridrestrictions, since higher power ranges could represent a negative impact on the low voltage (LV) grid in terms of PQ andEMS requirements [22]–[24]. Regarding the voltage level ofthe battery pack, the proposed design is focused on L-categoryvehicles (two-, three- and four-wheel vehicles such as motorcycles,mopeds, quads, and minicars), as the one studied in [25],but could be extended to other voltage levels.

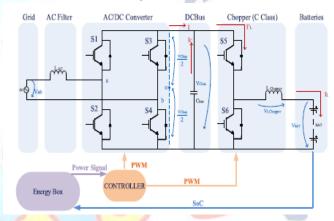

Figure 3: PEV charger topology.

The topology presented in Figure 3 is formed by three legsof two Insulated Gate Bipolar Transistors (IGBT), denoted bySj∈ {1, . . . , 6}. The IGBTs are used due to their good compromisecharacteristics associated with voltage, switching frequencyand current limits. These power switches are used for anAC/DC converter that operates as a controlled rectifier or as aninverter for G2V or V2G operation modes, respectively, and fora DC/DC converter (C class chopper) in which the power usedfor both modes is restricted, as discussed below. The features ofconverters meet the desired bi-directionality, where the chopperoperates as buck boost for G2V and V2G modes, respectively. Some passive elements for filtering and energystorage purposes are also designed and implemented, which are relevant for achieving proper system dynamics, stability and power quality.

CONTROLLERS DESIGN:

The controllers are PI-based and they aim at properly controllingthe IGBT switching following

voltage and current references.

the chopper controller design, assumptions weremade to facilitate circuit analysis: capacities in both sides of thechopper are high enough for considering constant voltage, low Lcapacity (when compared Cbus the capacity), and negligibleswitching losses. For establishing the control laws, it was necessary to determine the differential equations describing the energy demandof the converter (see (21)-(24)), according to Kirchhoff laws. Typically, the state variables in the converters are associated with the energy stored in capacitors and inductors, leading to Vcbus in the DC bus, VBAT in the batteries, and IL in the chopper inductor as displayed in Figure 4.

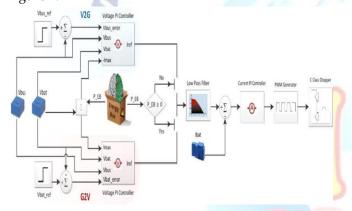

Figure 4: DC/DC converter controller architecture for V2G and G2V operation modes

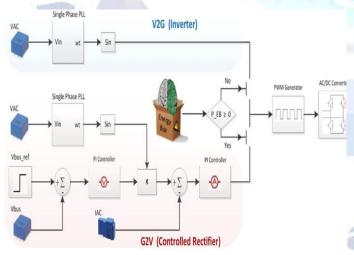

Figure 5: AC/DC converter controller architecture for V2G and G2V operation modes.

The controller for the rectifier is also PI based. A daisy chainof two PI controllers for DCbus voltage and AC current regulationis used. For AC current regulation, a phase-locked loop(PLL) is also used

providing AC current control reference asstated in [30]. This controller was firstly tuned using a poleplacement approach and then refined through experimental tests, being the final IGBT PWM signal provided by the unipolarPWM generator. The controller used for the AC/DC converter when this works as inverter is based only on the unipolar switching method. Aunit sinusoid reference provided by a PLL is used, which issynchronized with the voltage grid. In this operation mode, the DC bus available power was already restricted by the chopper, being at this point only mandatory inverting the DC bus voltage in a properway. Both AC/DC converter controllers are presented in Figure 5.

EXPERIMENTAL RESULTS:

The experimental results have been obtained using a reducedscale setup (with power levels 5 times lower than the full scale).It is important to note that in this reduced scale setup the DCBUSvoltage was stabilized around 108 V and PMax was ±460W, beingthe "Advisable Energy Levels" used forsizing, simulation and further full-scale implementation. Thissetup uses the LEM HY25-P and LV 25-P transducers for currentand voltage acquisition, respectively, presented in Figs. 3and 4. A DSP from NI for control and data logging purpose isalso used, jointly with other laboratory equipment and severalelectronic components, as presented in Figure 6.

CONCLUSION

A new BDC topology was presented to interface dual battery energy sources and high-voltagedc bus of different voltage levels. The circuit configuration, operation principles, analyses, and staticvoltage gains of the proposed BDC were discussed on the basis of different modes of power transfer. Simulation and experimental waveforms for a 1kW prototype system highlighted the performanceand feasibility of this proposed BDC topology. The highest conversion efficiencies were 97.25%,95.32%, 95.76%, and 92.67% for the high-voltage dc-bus energy-regenerative buck mode, lowvoltagedual-source-powering low-voltage dual-source boost mode (ES2 to ES1), and lowvoltagedual-source buck mode (ES1 to ES2), respectively. The results demonstrate that the proposed

BDC can be successfully applied in FC/HEV systems to produce hybrid power architecture. The comparison of fuzzy controller significantly smoothens the battery current that improves the battery life span and also reduces settling time and peak over shoot of the DC link volt<mark>age.</mark> Fuzzylogic controller regulates the power flow the battery by of a bidirectional means buck-boostconverter. The complete energy management system has been validated in MATLAB/SIMUINK withvariable solar irradiation profile.
